

## LeetCode 271 [Encode and Decode Strings]

Design an algorithm to encode a list of strings to a string. The encoded string is then sent over the network and is decoded back to the original list of strings.

s: [ab, a, abc, d]

es: [xxxxxxx]

ds: [ab, a, abc, d]

Approach 1: use extra character

s: [ab, b, c, abc]

es: [ab#b#c#abc]

ds: [ab, b, c, abc]

Time:  $O(n)$

Space:  $O(1)$

### Java solution

```
public String encode(List<String> strs) {  
    if (strs.isEmpty()) {  
        return Character.toString((char) 258);  
    }  
}
```

```
    String separate = Character.toString((char) 257);
```

```
    StringBuilder sb = new StringBuilder();
```

```
    for (String s: strs) {
```

```
        sb.append(s);
```

```
        sb.append(separate);
```

```
    }
```

```
    sb.deleteCharAt(sb.length() - 1);
```

```
    return sb.toString();  
}
```

```
public List<String> decode(String s) {
```

```
    if (s.equals(Character.toString((char) 258))) {
```

```
        return new ArrayList<>();
```

```
    }
```

```
    String separate = Character.toString((char) 257);
```

```
    return Arrays.asList(s.split(separate, -1));  
}
```

## Kotlin solution

```
fun encode(strs: List<String>): String {  
    if (strs.isEmpty()) return 258.toChar().toString()
```

```
    val separate = 257.toChar().toString()
```

```
    val sb = StringBuilder()
```

```
    for (s in strs) {
```

```
        sb.append(s)
```

```
        sb.append(separate)
```

```
    }
```

```
    sb.deleteCharAt(sb.length - 1)
```

```
    return sb.toString()
```

```
}
```

```
fun decode(s: String): List<String> {
```

```
    if (s == 258.toChar().toString()) return emptyList()
```

```
    val separate = 257.toChar().toString()
```

```
    return s.split(separate)
```

```
}
```
